New Results on the Game of N-Player Cutcake

Alessandro Cincotti

Abstract—The game of n-player Cutcake is the n-player variant of Cutcake, a classic combinatorial game. Even though determining the solution of Cutcake is trivial, solving n-player Cutcake is challenging because of the identification of queer games, i.e., games where no player has a winning strategy. New results about the classification of the instances of n-player Cutcake are presented.

Index Terms—combinatorial game, Cutcake, n-player game, queer game.

I. INTRODUCTION

THE game of Cutcake [1] is a classic two-player combinatorial game. Every instance of this game is defined as a set of rectangles of integer side-lengths with edges parallel to the x- and y-axes. The two players are often called Left and Right. A legal move for Left is to divide one of the rectangles into two rectangles of integer side-length by means of a single cut parallel to the x-axis and a legal move for Right is to divide one of the rectangles into two rectangles of integer side-length by means of a single cut parallel to the y-axis. Players take turns making legal moves until one of them cannot move. In the normal play convention, the first player unable to move is the loser. We recall that in the game of Cutcake the outcome for an n-player game, i.e., games where no player has a winning strategy, is a zero-game.

The game of Cutblock (a three-player version of Cutcake) was introduced by Propp in [2]. Cincotti [3], [4] presents a classification of the instances of Cutcake with an arbitrary finite number of players. Every instance of n-player Cutcake is defined as a set of n-cubes (or hypercubes) of integer side-lengths. A legal move for player i with 1 ≤ i ≤ n is to divide one of the n-cubes into two n-cubes of integer side-length, i.e.,

\[ [d_1, \ldots, d_i, \ldots, d_n] \rightarrow [d_1, \ldots, d_i, \ldots, d_n] + [d_1, \ldots, d_i, \ldots, d_n] \]

where \( d_i > 1 \), \( d_i > 0 \), \( d_i > 0 \), and \( d_i + d_i = d_i \).

Players take turns making legal moves in a cyclic fashion

\[ (p_1, p_2, \ldots, p_n) \]

where \( (p_1, p_2, \ldots, p_n) \) is a permutation of \( (1, \ldots, n) \). \( p_i = j \) means that player \( j \) makes the \( i \)th move, e.g., \( p_1 = 3 \) means that player 3 makes the first move. When one of the \( n \) players is unable to move then that player leaves the game and the remaining \( n-1 \) players continue playing in the same mutual order as before. The remaining player is the winner.

The paper is organized as follows. In Section 2, we recall the main definitions of n-player partizan games. In Section 3, we report the previous results about the classification of n-player Cutcake. In the fourth section, we show our new results and in the last section future work is indicated.

II. N-PLAYER PARTIZAN GAMES

For the sake of self-containment, we recall in this section the basic definitions and main results concerning n-player partizan games. Such a theory is an extension of Conway's theory of partizan games [5] and, as a consequence, it is both a theory of games and a theory of numbers.

Definition 1: If \( G_1, \ldots, G_n \) are any \( n \) sets of games previously defined, then \( \{G_1|\ldots|G_n\} \) is a game. All games are constructed in this way.

Let \( g = \{G_1|\ldots|G_n\} \) be a game. We denote by \( g_1, \ldots, g_n \), respectively, the typical elements of \( G_1, \ldots, G_n \). Therefore, the game can be written as \( g = \{g_1|\ldots|g_n\} \). The games \( g_1, g_2, \ldots, g_n \) will be called respectively the 1st, 2nd, \ldots, \( n \)th options of \( g \). We introduce \( n \) different relations \( (\geq_1, \ldots, \geq_n) \) representing players' evaluations of the games.

Definition 2: Let \( g \) and \( h \) be two games. We say that:

\[ g \geq_1 h \iff (\exists h_j \in G_j)(h \geq_1 g_j) \land (\forall i \in \{1, \ldots, n\}, j \neq i, h \geq_i g), \]

where \( i \in \{1, \ldots, n\} \).

We write \( g \not\geq_i h \) to mean that \( g \geq_1 h \) does not hold.

Definition 3: Let \( g \) and \( h \) be two games. We say that:

\[ g =_h h \iff (g \geq_1 h) \land (g \leq_1 h), \]

\[ g >_h h \iff (g \geq_1 h) \land (h \not\geq_i g), \]

\[ g <_h h \iff (h >_i g), \]

\[ g = h \iff (g =_i h), \forall i \in \{1, \ldots, n\}. \]

Definition 4: Let \( g \) be a game. We say that:

\[ g =_{i,j} 0 \iff (g =_i 0) \land (g =_j 0) \land (g <_k 0), \forall k \in \{1, \ldots, n\}, k \neq i, k \neq j, \]

\[ g =_{(i)} 0 \iff (g =_i 0) \land (g <_k 0), \forall k \in \{1, \ldots, n\}, k \neq i, \]

\[ g < 0 \iff (g <_k 0), \forall k \in \{1, \ldots, n\}. \]

A. Cincotti is with the School of Information Science, Japan Advanced Institute of Science and Technology, 1-1 Asahidai, Nomi, Ishikawa 923-1292 Japan (phone: +81-761-51-1293; e-mail: cincotti@jast.ac.jp).

(Advance online publication: 9 November 2011)
Definition 5: We say that two games \( g \) and \( h \) are identical \((g \equiv h)\) if their sets are identical, that is, if \( G_i \) is identical to \( H_j \) for all \( i, j \in \{1, \ldots, n\} \).

Definition 6: We define the sum of two games as follows:

\[
g + h = \{ g_1 + h_1, g_2 + h_2, \ldots, g_n + h_n \}
\]

A special case of games can be considered to define what we call numbers.

Definition 7: If \( G_1, G_2, \ldots, G_n \) are any \( n \) sets of numbers previously defined, and

\[
(\exists (g_i, g_j) \in G_i \times G_j, g_i \geq g_j, \forall i, j \in \{1, \ldots, n\}, i \neq j)
\]

then \( \{G_1 \cup G_2 \cup \ldots \cup G_n\} \) is a number. All numbers are constructed in this way.

Order relations and arithmetic operations on numbers are defined analogously to those for games. The most important distinction between numbers and general games is that numbers are totally ordered but games are not, e.g., there exist games \( g \) and \( h \) for which we have neither \( g \geq h \) nor \( h \geq g \).

All numbers can be classified in \( (n^2 + 3n + 4) / 2 \) classes as shown in Table II where \( n \geq 3 \) is the number of players, \( i, j \in \{1, \ldots, n\} \), and \( i \neq j \).

Table III and Table IV show all possibilities when we sum two numbers. The entries ‘?’ are unrestricted and indicate that different outcomes are possible.

For further details, please refer to [6].

### III. PREVIOUS RESULTS

Cincotti [4] presents a classification of the instances of \( n \)-player Cutcake using an \( n \)-player extension of partizan games as shown in Table V.

The case \( g = (i) \) is particular interesting. By previous results, we know that when player \( i \) makes the first move, either player \( i \) has a winning strategy or the game is queer, i.e., no player has a winning strategy. In a previous work [7], we presented some sufficient conditions to guarantee a win for player \( i \) when \( n = 3 \).

In the next section, we generalize the previous result for \( n \geq 4 \). Moreover, we give some sufficient conditions to guarantee a win for player \( i \) when \( g < 0 \).

### IV. NEW RESULTS

**Theorem 1:** Let \( g \) be a general instance of \( n \)-player Cutcake where every \( n \)-cube \( [d_1, \ldots, d_n] \) satisfies one of the following conditions:

\[
\left[ \log_2 d_i \right] \geq \sum_{j \neq i} \left[ \log_2 d_j \right] \geq 0 \,
\]

If the number of \( n \)-cubes satisfying the second condition is at most \( n - 2 \) and player \( i \) has just moved in \( g \), then player \( i \) has a winning strategy.

**Proof:** If player \( j \), with \( j \neq i \), moves in an \( n \)-cube \( B \) satisfying the first condition, then he/she will create at least a new \( n \)-cube \( A_1 \) as shown in Table VI. If player \( j \), with \( j \neq i \), moves in an \( n \)-cube \( B \) satisfying the second condition, then he/she will create two new \( n \)-cubes \( B_1 \) and \( B_2 \) satisfying the first condition as shown in Table VII.

By hypothesis, the number of \( n \)-cubes satisfying the second condition is at most \( n - 2 \). Therefore, at least one player \( j \), with \( j \neq i \), will move in an \( n \)-cube satisfying the first condition and, as a consequence, at least one \( n \)-cube

\[ [e_1, e_2, \ldots, e_n] \geq 0 \]

Table VII | OUTCOMES FOR B1 AND B2 |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>( B &lt; 0 )</td>
<td>( B_1 = (i) )</td>
</tr>
<tr>
<td>( B &gt; 0 )</td>
<td>( B_1 = (i) )</td>
</tr>
<tr>
<td>( B = 0 )</td>
<td>( B_1 = (i) )</td>
</tr>
</tbody>
</table>

(Advance online publication: 9 November 2011)
will be created. If player \( i \) moves in
\[
[e_1, \ldots, e_i, \ldots, e_n] >_i 0
\]
then he/she is always able to create two new n-cubes satisfying the first condition as shown in Table VIII.

At the end of the first round, i.e., after that all the players have made one move, all the hypothesis of the theorem are still satisfied and therefore, by the inductive hypothesis, player \( i \) has a winning strategy. ■

**Corollary 1:** Let \( [d_1, \ldots, d_n] =_{(i)} 0 \) be an n-cube of n-player Cutcake where \( d_j = 2^j, j \geq 1, j \neq i, n \geq 4 \). Then, when player \( i \) makes the first move, he/she has a winning strategy.

**Proof:** If player \( i \) moves
\[
[d_1, \ldots, d_i, \ldots, d_n] \rightarrow [d_1, \ldots, d_i/2, \ldots, d_n] + [d_1, \ldots, d_i/2, \ldots, d_n]
\]
then
\[
\lfloor \log_2(d_i/2) \rfloor = \sum_{j \neq i} \lfloor \log_2 d_j \rfloor - 1
\]
and
\[
[d_1, \ldots, d_i/2, \ldots, d_n] < 0
\]
Moreover, either
\[
\lfloor \log_2(d_i/2) \rfloor = \sum_{j \neq i} \lfloor \log_2 d_j \rfloor - 1
\]
and
\[
[d_1, \ldots, d_i/2, \ldots, d_n] < 0
\]
or
\[
\lfloor \log_2(d_i/2) \rfloor = \sum_{j \neq i} \lfloor \log_2 d_j \rfloor
\]
and
\[
[d_1, \ldots, d_i/2, \ldots, d_n] =_{(i)} 0
\]
In both cases, by Theorem 1, player \( i \) has a winning strategy. We observe that the hypothesis \( n \geq 4 \) is necessary only when we have two n-cubes satisfying the second condition; otherwise the hypothesis \( n \geq 3 \) is sufficient. ■

**Theorem 2:** Let \( [d_1, \ldots, d_n] < 0 \) be an n-cube of n-player Cutcake where
\[
\lfloor \log_2 d_i \rfloor = \sum_{j \neq i} \lfloor \log_2 d_j \rfloor - 1, d_p i = 2^t, t \geq 1
\]
If \( p_1 \neq i \) and \( p_2 \neq i \), then player \( i \) has a winning strategy.

**Proof:** In the beginning, player \( p_1 \) moves in
\[
[d_1, \ldots, d_n]
\]
and he/she will create two new n-cubes \( A_1 \) and \( A_2 \). As shown in Table IX, the game \( A_1 + A_2 \) has three different possible outcomes. In any of these three cases, when player \( p_2 \) moves in \( A_1 + A_2 \), the game will become \( >_i 0 \) therefore, player \( i \) has a winning strategy. ■

\hline
\end{array}
\]

**V. Future Work**

In this paper, we presented some sufficient conditions to guarantee a win for player \( i \) in the game \( g =_{(i)} 0 \) when he/she makes the first move. Moreover, we gave some sufficient conditions to guarantee a win for player \( i \) in the game \( g < 0 \) when he/she makes neither the first nor the second move.

Future work will concern the resolution of the following open problems:

- To find some sufficient conditions to identify queer games in the case \( g =_{(i)} 0 \) when player \( i \) makes the first move.
- To find some sufficient conditions to identify queer games in the case \( g < 0 \).
