Abstract—The paper introduces a smoothing method to the lower order penalty function for constrained optimization problems. It is shown that, under some mild conditions, an optimal solution of the smoothed penalty problem is an approximate optimal solution of the original problem. Based on the smoothed penalty function, an algorithm is presented and its convergence is proved under some mild assumptions. Numerical examples show that the presented algorithm is effective.

Index Terms—constrained optimization problem, penalty function method, exact penalty function, smoothing method.

I. INTRODUCTION

Consider the constrained optimization problem:

\[(P) \quad \min \ f(x) \]
\[\text{s.t. } g_i(x) \leq 0, \quad i = 1, 2, \ldots, m, \quad x \in \mathbb{R}^n,\]

where \(f, g_i : \mathbb{R}^n \rightarrow \mathbb{R}, \quad i \in I = \{1, 2, \ldots, m\}\) are real valued functions, and \(X_0 = \{x \in \mathbb{R}^n \mid g_i(x) \leq 0, \quad i \in I\}\) is the feasible set to \((P)\). Constrained optimization problems have been applied in many fields, such as including optimal control, engineering, national defence, economy, and finance etc. Up to now, the methods of solving the constrained optimization problems have been well studied in the literatures. The use of penalty functions to solve constrained optimization problems is generally attributed to Courant. The significant progress in solving many practical nonlinear constrained optimization problems by using exact penalty function methods have been introduced in literatures \([1], [2], [3], [4], [5], [6], [7]\). Zangwill \([7]\) proposed the classic \(l_1\) exact penalty function as follows:

\[F_{\sigma}(x) = f(x) + \sigma \sum_{i=1}^{m} g_i^+(x), \tag{1}\]

where \(g_i^+(x) = \max\{0, g_i(x)\}, \quad i \in I\) and \(\sigma > 0\) is a penalty parameter. It is known from the theory of ordinary constrained optimization that the \(l_1\) exact penalty function is a better candidate for penalization. However, it is not a smooth function and causes some numerical instability problems in its implementation when the value of the penalty parameter \(\sigma\) becomes larger. Thus, smoothing methods for smoothing the exact penalty function attract much attention, see, e.g., \([8], [9], [10], [11], [12], [13], [14], [15], [16], [17]\). In recent years, the lower order penalty function

\[F_{\sigma}^k(x) = f(x) + \sigma \sum_{i=1}^{m} [g_i^+(x)]^k, \tag{2}\]

where \(k \in (0, 1)\) and \(\sigma > 0\) have been introduced in \([12], [13], [15]\). Obviously, when \(k = 1\), the lower order penalty function \((2)\) is reduced to the exact penalty function \((1)\). Meng et al. \([12]\) discussed two smoothing approximations to the lower order penalty function for inequality constrained optimization. Meng et al. \([13]\) discussed a smoothing method of lower order penalty function and gave a robust SQP method for \((P)\) by integrating the smoothed penalty function with the SQP method. Wu et al. \([15]\) proposed the \(\epsilon\)-smoothing of \((2)\), and got a modified exact penalty function under some mild conditions. Error estimates of the optimal value of the smoothed penalty problem and that of the original penalty problem are obtained.

Based on the lower order penalty function, this paper introduces a smoothing lower order penalty function method which differs from the smoothing penalty function methods in \([12], [13], [15]\), and proposes a corresponding algorithm for solving \((P)\). Numerical results show that this algorithm is of good convergence and is efficient in solving some constrained optimization problems.

The rest of this paper is organized as follows. In Section II, we propose a new smoothing function to the exact penalty function \((2)\), and discuss its some fundamental properties. In Section III, an algorithm based on the smoothing lower order penalty function is proposed and its global convergence presented, with some numerical examples are given.

II. SMOOTHED LOWER ORDER METHOD

Consider \(p^k(v) : \mathbb{R} \rightarrow \mathbb{R} : \)

\[p^k(v) = \begin{cases} 
0 & \text{if } v < 0, \\
\epsilon^k & \text{if } v \geq 0,
\end{cases}\]

where \(k \in (0, 1)\). Then,

\[F_{\sigma}^k(x) = f(x) + \sigma \sum_{i=1}^{m} p^k(g_i(x)). \tag{3}\]

The corresponding penalty problem to \((3)\) is defined as follows,

\[(P_{\sigma}) \quad \min \ F_{\sigma}^k(x) \]
\[\text{s.t. } x \in \mathbb{R}^n.\]

For \(k \in (0, 1)\) and any \(\epsilon > 0\), we define function \(p_{\epsilon, \sigma}^k(v)\) as

\[p_{\epsilon, \sigma}^k(v) = \begin{cases} 
0 & \text{if } v < 0, \\
\frac{m^2 \sigma^2 v^{3k}}{6 \epsilon^3} & \text{if } 0 \leq v < \left(\frac{\epsilon}{m \sigma}\right)^{\frac{1}{k}}, \\
\frac{\epsilon^k + \frac{m^2 \sigma^2 v^{-k}}{2m^2 \sigma^2} - \frac{4e}{3m \sigma}}{2m^2 \sigma^2} & \text{if } v \geq \left(\frac{\epsilon}{m \sigma}\right)^{\frac{1}{k}},
\end{cases}\]

where \(\epsilon\) is a smoothing parameter and \(\sigma > 0\) is given.

(Advance online publication: 15 February 2016)
Remark 2.1. Obviously, $p_{\epsilon,\sigma}^k(v)$ has the following attractive properties:

(i) $p_{\epsilon,\sigma}^k(v)$ is twice continuously differentiable for $\frac{2}{3} < k < 1$ on $R$, where

$$[p_{\epsilon,\sigma}^k(v)]'' = \begin{cases} 0 & \text{if } v < 0, \\ \frac{km^2\sigma^2v^{k-1}}{2\epsilon^2} & \text{if } 0 \leq v < \left(\frac{\epsilon}{m\sigma}\right)^{\frac{1}{k}}, \\ kv^{k-1} - \frac{k^2v^{k-2}}{2m^2\sigma^2} & \text{if } v \geq \left(\frac{\epsilon}{m\sigma}\right)^{\frac{1}{k}}. \end{cases}$$

and

$$[p_{\epsilon,\sigma}^k(v)]''' = \begin{cases} 0 & \text{if } v < 0, \\ \frac{k(3k-1)m^2\sigma^2v^{k-2}}{2\epsilon^2} & \text{if } 0 \leq v < \left(\frac{\epsilon}{m\sigma}\right)^{\frac{1}{k}}, \\ (k(k-1)v^{k-2} + \frac{k(k+1)^2v^{k-2}}{2m^2\sigma^2}) & \text{if } v \geq \left(\frac{\epsilon}{m\sigma}\right)^{\frac{1}{k}}. \end{cases}$$

(ii) $\lim_{v \to 0} p_{\epsilon,\sigma}^k(v) = p^k(v)$.

(iii) $p^k(v) \geq p_{\epsilon,\sigma}^k(v)$, $\forall v \in R$.

Figure 1 shows the behavior of $p^k(v)$ and $p_{\epsilon,\sigma}^k(v)$. Assume that $f, g_i (i \in I)$ are continuously differentiable functions. Let

$$F_{\epsilon,\sigma}^k(x) = f(x) + \sigma \sum_{i=1}^m p_{\epsilon,\sigma}^k(g_i(x)).$$

Clearly, $F_{\epsilon,\sigma}^k(x)$ is continuously differentiable at any $x \in R^n$. Consider the following smoothed penalty problem:

$$(SP_{\epsilon,\sigma}) \quad \min F_{\epsilon,\sigma}^k(x) \quad \text{s.t. } x \in R^n.$$  

Lemma 2.1. We have

$$0 \leq F_{\sigma}^k(x) - F_{\epsilon,\sigma}^k(x) \leq \frac{4\epsilon}{3}$$

for any given $x \in R^n$, $\epsilon > 0$ and $\sigma > 0$, where $F_{\sigma}^k(x)$ and $F_{\epsilon,\sigma}^k(x)$ are given in (3) and (4) respectively.

Proof For any $x \in R^n$, $\epsilon > 0$, $\sigma > 0$, we have

$$F_{\sigma}^k(x) - F_{\epsilon,\sigma}^k(x) = \sigma \sum_{i=1}^m (p^k(g_i(x)) - p_{\epsilon,\sigma}^k(g_i(x))).$$

Note that

$$p^k(g_i(x)) - p_{\epsilon,\sigma}^k(g_i(x)) = \begin{cases} 0 & \text{if } g_i(x) < 0, \\ 0 \leq g_i(x) < \frac{m^2\sigma^2(g_i(x))^{\frac{3k}{2}}}{6\epsilon^2} & \left(\frac{\epsilon}{m\sigma}\right)^{\frac{1}{k}}, \\ 0 \leq \frac{4\epsilon}{3m\sigma} - \frac{2m^2\sigma^2(g_i(x))^{-k}}{2m^2\sigma^2} \leq 4\epsilon & \text{if } g_i(x) \geq \left(\frac{\epsilon}{m\sigma}\right)^{\frac{1}{k}}. \end{cases}$$

for any $i = 1, 2, \ldots, m$. That is,

$$0 \leq p^k(g_i(x)) - p_{\epsilon,\sigma}^k(g_i(x)) \leq \frac{4\epsilon}{3m\sigma}.$$  

Thus,

$$0 \leq \sum_{i=1}^m (p^k(g_i(x)) - p_{\epsilon,\sigma}^k(g_i(x))) \leq \frac{4\epsilon}{3\sigma},$$

which implies

$$0 \leq \sigma \sum_{i=1}^m (p^k(g_i(x)) - p_{\epsilon,\sigma}^k(g_i(x))) \leq \frac{4\epsilon}{3}.$$

Therefore,

$$0 \leq F_{\sigma}^k(x) - F_{\epsilon,\sigma}^k(x) \leq \frac{4\epsilon}{3}.$$  

The proof is completed.

Based on the Lemma 2.1, we have the following two theorems.

Theorem 2.1. Let $\{\epsilon_j\} \to 0$, $\forall \epsilon_j > 0$, and assume $x_j$ is a solution to $(SP_{\epsilon_j,\sigma})$ for some $\sigma > 0$. Let $x'$ be an accumulation point of the sequence $\{x_j\}$. Then $x'$ is an optimal solution to $(P_\sigma)$.

Proof Since $x_j$ is a solution to problem $(SP_{\epsilon_j,\sigma})$, we have

$$F_{\epsilon_j,\sigma}^k(x_j) \leq F_{\epsilon_j,\sigma}^k(x).$$

By Lemma 2.1, we have

$$F_{\sigma}^k(x_j) \leq F_{\epsilon_j,\sigma}^k(x_j) + \frac{4\epsilon_j}{3},$$

$$F_{\epsilon_j,\sigma}^k(x_j) \leq F_{\sigma}^k(x_j).$$

It follows

$$F_{\sigma}^k(x_j) \leq F_{\epsilon_j,\sigma}^k(x_j) + \frac{4\epsilon_j}{3}$$

$$\leq F_{\sigma}^k(x_j) + \frac{4\epsilon_j}{3}.$$  

Since $\{\epsilon_j\} \to 0$ and $x'$ be an accumulation point of the sequence $\{x_j\}$, we have

$$F_{\sigma}^k(x') \leq F_{\sigma}^k(x).$$

The proof is completed.

Theorem 2.2. For some $\sigma > 0$ and $\epsilon > 0$, let $x^*_\sigma$ be an optimal solution to $(P_\sigma)$ and $x^*_{\epsilon,\sigma}$ be an optimal solution to $(SP_{\epsilon,\sigma})$. Then,

$$0 \leq F_{\sigma}^k(x^*_\sigma) - F_{\epsilon,\sigma}^k(x^*_{\epsilon,\sigma}) \leq \frac{4\epsilon}{3}.$$  

If both $x^*_\sigma$ and $x^*_{\epsilon,\sigma}$ are feasible to $(P)$, then

$$f(x^*_{\epsilon,\sigma}) \leq f(x^*_{\sigma}) \leq f(x^*_{\epsilon,\sigma}) + \frac{4\epsilon}{3}. $$

(Advance online publication: 15 February 2016)
Proof By Lemma 2.1, for \( \sigma > 0 \) and \( \epsilon > 0 \), we have that
\[
0 \leq F^k_{\sigma}(x^*_\epsilon) - F^k_{\sigma}(x^*_\epsilon) \\
\leq F^k_{\sigma}(x^*_\epsilon) - F^k_{\sigma}(x^*_\epsilon) \\
\leq F^k_{\sigma}(x^*_\epsilon) - F^k_{\sigma}(x^*_\epsilon) \\
\leq 4\epsilon / 3.
\]
That is,
\[
0 \leq F^k_{\sigma}(x^*_\epsilon) - F^k_{\sigma}(x^*_\epsilon) \leq 4\epsilon / 3
\]
and
\[
0 \leq \left\{ f(x^*_\epsilon) + \sigma \sum_{i=1}^{m} p^k_i(g_i(x^*_\epsilon)) \right\} \\
- \left\{ f(x^*_\epsilon) + \sigma \sum_{i=1}^{m} p^k_i(g_i(x^*_\epsilon)) \right\} \leq 4\epsilon / 3.
\]
Furthermore, if \( x^*_\epsilon \) and \( x^*_\epsilon \) are feasible to (P), then
\[
\sum_{i=1}^{m} p^k_i(g_i(x^*_\epsilon)) = \sum_{i=1}^{m} p^k_i(g_i(x^*_\epsilon)) = 0.
\]
Therefore,
\[
0 \leq f(x^*_\epsilon) - f(x^*_\epsilon) \leq 4\epsilon / 3.
\]
That is,
\[
f(x^*_\epsilon) \leq f(x^*_\epsilon) \leq f(x^*_\epsilon) + 4\epsilon / 3.
\]
The proof is completed.

Definition 2.1. A point \( x^*_\epsilon \in \mathbb{R}^n \) is called \( \epsilon \)-feasible solution to (P) if
\[
g_i(x^*_\epsilon) \leq \epsilon, \quad i = 1, 2, \ldots, m.
\]

Definition 2.2. For \( \pi \in \mathbb{R}^n \), a point \( \gamma \in \mathbb{R}^m \) is called a Lagrange multiplier vector corresponding to \( \pi \) if \( \pi \) and \( \gamma \) satisfy that
\[
\nabla f(\pi) = -\sum_{i=1}^{m} \gamma_i \nabla g_i(\pi),
\]
\[
\gamma_i g_i(\pi) = 0, \quad g_i(\pi) \leq 0, \quad \gamma_i \geq 0, \quad i \in I.
\]

Theorem 2.3. Suppose that \( f, g_i \quad (i \in I) \) in (P) are convex. Let \( \pi \) be an optimal solution to (P) and \( x^*_\epsilon \) be an optimal solution to \((SP_{\epsilon, \sigma})\). If \( x^*_\epsilon \) is feasible to (P), and \( \pi \) is a Lagrange multiplier vector corresponding to \( x^*_\epsilon \), then
\[
f(\pi) \leq f(x^*_\epsilon) \leq f(\pi) + 4\epsilon / 3
\]
for any \( \epsilon > 0 \).

Proof By the convexity of \( f, g_i \quad (i \in I) \), we have
\[
f(\pi) \geq f(x^*_\epsilon) + \nabla f(x^*_\epsilon)^T(\pi-x^*_\epsilon),
\]
\[
g_i(\pi) \geq g_i(x^*_\epsilon) + \nabla g_i(x^*_\epsilon)^T(\pi-x^*_\epsilon).
\]
By (3), (8), (9), (11) and (12), we have
\[
F^k_{\sigma}(\pi) = f(\pi) + \sigma \sum_{i=1}^{m} p^k_i(g_i(\pi)) \\
\geq f(x^*_\epsilon) + \nabla f(x^*_\epsilon)^T(\pi-x^*_\epsilon) \\
= f(x^*_\epsilon) - \sum_{i=1}^{m} \gamma_i \nabla g_i(x^*_\epsilon)^T(\pi-x^*_\epsilon) \\
\geq f(x^*_\epsilon) - \sum_{i=1}^{m} \gamma_i g_i(\pi) \\
= f(x^*_\epsilon) - \sum_{i=1}^{m} \gamma_i g_i(\pi) \\
\geq f(x^*_\epsilon).
\]
By Lemma 2.1, we have
\[
F^k_{\sigma}(\pi) \leq F^k_{\sigma}(\pi) + 4\epsilon / 3.
\]
It follows
\[
\begin{align*}
f(x^*_\epsilon) & \leq F^k_{\sigma}(\pi) + 4\epsilon / 3 \\
& = f(\pi) + \sigma \sum_{i=1}^{m} p^k_i(g_i(\pi)) + 4\epsilon / 3 \\
& = f(\pi) + 4\epsilon / 3.
\end{align*}
\]
Since \( x^*_\epsilon \) is feasible to problem (P), that
\[
f(\pi) \leq f(x^*_\epsilon).
\]
Thus,
\[
f(\pi) \leq f(x^*_\epsilon) \leq f(\pi) + 4\epsilon / 3.
\]
The proof is completed.

Theorem 2.2 show that an approximate solution to \((SP_{\epsilon, \sigma})\) is also an approximate solution to \((P_\sigma)\) when the error \( \epsilon \) is small enough. By Theorem 2.3, under some mild conditions, an optimal solution to \((SP_{\epsilon, \sigma})\) becomes an approximately optimal solution to (P). Therefore, we may obtain an approximately optimal solution to (P) by solving problem \((SP_{\epsilon, \sigma})\).

III. ALGORITHM AND NUMERICAL EXAMPLES

In this section, we propose an algorithm to solve problem (P) via solving the problem \((SP_{\epsilon, \sigma})\), defined as Algorithm I.

Algorithm I

Step 1: Given a point \( x^0_\epsilon \in \mathbb{R}^n \). Choose \( \epsilon_1 > 0, \sigma_1 > 0, 0 < \gamma < 1, \beta > 1 \) and \( \epsilon > 0 \). Let \( j = 1 \), and go to Step 2.

Step 2: Solve the following problem:
\[
(SP_{\epsilon, \sigma}) \min_{x \in \mathbb{R}^n} F^k_{\epsilon, \sigma}(x) = f(x) + \sigma \sum_{i=1}^{m} p^k_{\epsilon, \sigma}(g_i(x))
\]
starting from the point \( x^0_\epsilon \). Let \( x^*_\epsilon, \sigma \) be an optimal solution obtained \((SP_{\epsilon, \sigma})\) is obtained by the BFGS method given in [19]).

Step 3: If \( x^*_\epsilon, \sigma \) is \( \epsilon \)-feasible to (P), then stop. Otherwise, let \( \sigma_{j+1} = \beta \sigma_j, \epsilon_{j+1} = \gamma \epsilon_j, x^0_{j+1} = x^*_\epsilon, \sigma_j \) and \( j = j + 1 \), then go to Step 2.
Remark 3.1. In this Algorithm I, from \(0 < \gamma < 1\), \(\beta > 1\), the sequence \(\{\epsilon_j\} \to 0\) and the sequence \(\{\sigma_j\} \to +\infty\), as \(j \to +\infty\).

Under mild conditions, we now prove the convergence of the Algorithm I.

Theorem 3.1. For \(\frac{1}{\beta} < k < 1\), suppose that the set \[ \arg \min_{x \in R^n} F^k_{\epsilon,\sigma}(x) \neq \emptyset \] (13) for any \(\epsilon \in (0, \epsilon_1]\), and \(\sigma \in [\sigma_1, +\infty)\). Let \(\{x'_j\}\) be a sequence generated by Algorithm I. If \(\{x'_j\}\) has limit point, then any limit point of \(\{x'_j\}\) is an optimal solution to (P).

Proof (i) First, we will prove that \(\{x'_j\}\) is bounded. Note that

\[
F^k_{\epsilon,\sigma}(x'_j) = f(x'_j) + \sigma_j \sum_{i=1}^{m} p^k_{\epsilon_i,\sigma_j}(g_i(x'_j)), \quad j = 0, 1, 2, \ldots ,
\] (15) and by the definition of \(p^k_{\epsilon,\sigma}(v)\), we have

\[
\sum_{i=1}^{m} p^k_{\epsilon_i,\sigma_j}(g_i(x'_j)) \geq 0.
\] (16)

Suppose to the contrary that \(\{x'_j\}\) is unbounded and without loss of generality, \(\|x'_j\| \to +\infty\) as \(j \to +\infty\). Then,

\[
\lim_{j \to +\infty} f(x'_j) = +\infty, \quad \text{and from (15) and (16), we have}
\] (17)

\[
F^k_{\epsilon,\sigma}(x'_j) \geq f(x'_j) \to +\infty, \quad \sigma_j > 0,
\] which contradicts with \(\{F^k_{\epsilon,\sigma}(x'_j)\}\) is bounded. Thus, \(\{x'_j\}\) is bounded.

(ii) Next, we will prove that any limit point \(x'\) of \(\{x'_j\}\) is feasible to (P).

For \(x \in R^n\), let

\[
I^+_c = \{i \mid g_i(x) \geq \left(\frac{\epsilon}{m\sigma_j}\right)^{\frac{1}{k}}, \quad i = 1, 2, \ldots , m\},
\] (18)

\[
I^-_c = \{i \mid g_i(x) < \left(\frac{\epsilon}{m\sigma_j}\right)^{\frac{1}{k}}, \quad i = 1, 2, \ldots , m\}.
\]

Without loss of generality, assume that \(\lim_{j \to +\infty} x'_j = x'\). Suppose to the contrary that \(x' \notin X_0\), then there exist some \(i \in I\), such that \(g_i(x') \geq 1\). Note that

\[
F^k_{\epsilon,\sigma}(x'_j) = f(x'_j) + \sigma_j \sum_{i \in I^+_c} \frac{m^2 \sigma^2_j (g_i(x'_j))^{2k}}{6 \epsilon^2_j} + \sigma_j \sum_{i \in I^-_c} \left(\frac{g_i(x'_j)^k + \frac{e^2_j g_i(x'_j)^{-k}}{2m^2 \sigma^2_j} - \frac{4\epsilon_j}{3m \sigma_j}}{2m^2 \sigma^2_j} \right) \nabla g_i(x'_j) = 0.
\] (19)

Since \(g_i(x') \geq 1\), then for any sufficiently large \(j\), the set \(\{i \mid g_i(x') \geq 1\}\) is not empty. Then there exists an \(i' \in I\) that satisfies \(g_i(x'_j) \geq 1\). If \(j \to +\infty, \sigma_j \to +\infty, \epsilon_j \to 0\), it follows from (19) that \(F^k_{\epsilon,\sigma}(x'_j) \to +\infty\), which contradicts with \(\{F^k_{\epsilon,\sigma}(x'_j)\}\) is bounded. Therefore, \(x'\) is feasible to (P).

(iii) Finally, we prove that (14) holds. By Step 2 in Algorithm I, we have \(\nabla F^k_{\epsilon,\sigma}(x'_j) = 0\), that is

\[
\nabla f(x'_j) + \sigma_j \sum_{i \in I^+_c} \frac{km^2 \sigma^2_j (g_i(x'_j))^{2k-1}}{2 \epsilon^2_j} \nabla g_i(x'_j)
\] (20)

\[
+ \sigma_j \sum_{i \in I^-_c} \left(\frac{k(g_i(x'_j))^{k-1} - \frac{km^2 \sigma^2_j (g_i(x'_j))^{-k-1}}{2m^2 \sigma^2_j}}{2m^2 \sigma^2_j} \right) \nabla g_i(x'_j) = 0.
\] (21)

which implies

\[
\nabla f(x'_j) + \sigma_j \sum_{i \in I^+_c} \frac{km^2 \sigma^2_j [p^k_h g_i(x'_j)]^{\frac{4k-1}{k}}}{2 \epsilon^2_j} \nabla g_i(x'_j)
\]

\[
+ \sigma_j \sum_{i \in I^-_c} \left[\frac{k[p^k_h g_i(x'_j)]^{\frac{4k-1}{k}}} {2m^2 \sigma^2_j} \right] \nabla g_i(x'_j) = 0.
\] (22)
Let
\[
\alpha_j = 1 + \sigma_j \sum_{i \in I^*_j} \frac{km^2\sigma_j^2 [p^k (g_i(x^*_j))] \frac{bk}{k-1}}{2\sigma_j^2},
\]
\[
+ \sigma_j \sum_{i \in I^*_j} \left( k [p^k (g_i(x^*_j))] \frac{bk}{k-1} - \frac{km^2\sigma_j^2 [p^k (g_i(x^*_j))] \frac{bk}{k-1}}{2m^2\sigma_j^2} \right),
\]
\( j = 0, 1, 2, \ldots, \) then \( \alpha_j > 1. \) From (18), we have
\[
\frac{1}{\alpha_j} \nabla f(x^*_j) + \sum_{i \in I^*_j} \frac{km^2\sigma_j^2 [p^k (g_i(x^*_j))] \frac{bk}{k-1}}{2\sigma_j^2} \nabla g_i(x^*_j)
\]
\[
+ \sum_{i \in I^*_j} \left( \frac{\sigma_j [p^k (g_i(x^*_j))] \frac{bk}{k-1}}{\alpha_j} - \frac{km^2\sigma_j^2 [p^k (g_i(x^*_j))] \frac{bk}{k-1}}{2m^2\sigma_j^2} \right) \nabla g_i(x^*_j) = 0. \tag{19}
\]

Let
\[
k^3 = \frac{1}{\alpha_j},
\]
\[
\nu^*_i = \frac{km^2\sigma_j^2 [p^k (g_i(x^*_j))] \frac{bk}{k-1}}{2\sigma_j^2}, \quad i \in I^*_j,
\]
\[
\nu_i = \frac{\sigma_j [p^k (g_i(x^*_j))] \frac{bk}{k-1}}{\alpha_j} - \frac{km^2\sigma_j^2 [p^k (g_i(x^*_j))] \frac{bk}{k-1}}{2m^2\sigma_j^2}, \quad i \in I^*_j,
\]
\[
\nu_i = 0, \quad i \in I \setminus (I^*_j \cup I^*_j).
\]

Then,
\[
\frac{1}{\alpha_j} \nabla f(x^*_j) + \sum_{i \in I} \frac{\nu_i}{\alpha_j} \nabla g_i(x^*_j) = 0,
\]
which implies
\[
\nabla f(x^*_j) + \sum_{i \in I} \frac{\nu_i}{\alpha_j} \nabla g_i(x^*_j) = 0.
\]

Let \( \nu_i = \frac{\nu_i}{\alpha_j}, \) it follows
\[
\nabla f(x^*_j) + \sum_{i \in I} \nu_i \nabla g_i(x^*_j) = 0, \quad \nu_i \geq 0.
\]

The proof is completed.

The rest of this paper we solve three numerical examples to illustrate the efficiency of Algorithm I. In each example we let \( k = \frac{3}{4} \) and \( \epsilon = 10^{-6}, \) then the numerical results with Algorithm I on MATLAB are given as follows.

**Example 3.1.** Consider ([12], Example 4.2)

(P1) \( \min f(x) = x_1^2 + x_2^2 + 2x_3^2 + x_4^2 - 5x_1 - 5x_2 - 21x_3 + 7x_4 \)
\[
\text{s.t. } g_1(x) = 2x_1^2 + x_2^2 + x_3^2 + 2x_1 + x_2 + x_4 - 5 \leq 0,
\]
\[
g_2(x) = x_1^2 + x_2^2 + x_3^2 + x_4 + x_3 - x_2 + x_4 - 4 \leq 0,
\]
\[
g_3(x) = x_1^2 + 2x_2^2 + x_3^2 + 2x_2^2 - x_1 - x_4 - 10 \leq 0.
\]

Let \( x_0 = (0, 0, 0, 0), \ \sigma_1 = 10, \ \beta = 2, \ \epsilon_1 = 1.0, \ \gamma = 0.05. \) The results of Algorithm I for solving (P1) are given in Table I.

As shown in Table I, it is found that Algorithm I yields an approximate optimal solution
\[
x^*_1 = (0.170446, 0.834248, 2.008753, -0.964559)
\]
to (P1) at the 2' th iteration with objective function value \( f(x^*_1) = -44.233627. \) It is easy to check that \( x^*_2 = (0.169234, 0.835656, 2.008690, -0.964901) \) is an approximate optimal solution of (P1) with objective function value \( f(x^*_2) = -44.233582. \) The solution we obtained is slightly better than the solution obtained in the 4' th iteration by method in [12].

**Example 3.2.** Consider ([20], Example 4.1)

(P2) \( \min f(x) = x_1^2 + x_2^2 - \cos (17x_1) - \cos (17x_2) + 3 \)
\[
\text{s.t. } g_1(x) = (x_1 - 2)^2 + x_2^2 - 1.62 \leq 0,
\]
\[
g_2(x) = x_1^2 + (x_2 - 3)^2 - 2.72 \leq 0.
\]

Let \( x_0 = (0, 0), \ \sigma_1 = 10, \ \beta = 2, \ \epsilon_1 = 0.01, \ \gamma = 0.01. \) The results of Algorithm I for solving (P2) are given in Table II.

As shown in Table II, it is found that Algorithm I yields an approximate optimal solution \( x^* = (0.725379, 0.399267) \) to (P2) at the 2' th iteration with objective function value \( f(x^*) = 1.837574. \) From [20], we know that \( x^* = (0.7255, 0.3993) \) is a global solution of (P2) with global optimal value \( f(x^*) = 1.8376. \) The solution we obtained is slightly better than the solution obtained by method in [20].

**Example 3.3.** Consider ([16], Example 3.3)

(P3) \( \min f(x) = -2r_1 - 6x_2 + x_1^2 - 2x_1x_2 + 2x_2^2 \)
\[
\text{s.t. } g_1(x) = x_1 + x_2 - 2 \leq 0,
\]
\[
g_2(x) = -x_1 + 2x_2 - 2 \leq 0.
\]

Let \( x_0 = (0, 0), \ \sigma_1 = 10, \ \beta = 8, \ \epsilon_1 = 0.01, \ \gamma = 0.02. \) The results of Algorithm I for solving (P3) are given in Table III.

As shown in Table III, it is found that Algorithm I yields an approximate optimal solution \( x^* = (0.800003, 1.199997) \) to (P3) at the 3' th iteration with objective function value \( f(x^*) = -7.200000. \) From [16], we know that \( x^* = (0.8000, 1.2000) \) is a global solution of (P3) with global optimal value \( f(x^*) = -7.2000. \) The solution we obtained is similar with the solution obtained in the 4' th iteration by method in [16].

**ACKNOWLEDGMENT**

The author would like to thank the editors and all of the anonymous reviewers for their valuable comments and suggestions, which were strongly helped improve the quality of the paper.
