Sequence Diagram Generation with Model Transformation Technology

Photchana Sawprakhon, Yachai Limpiyakorn

Abstract—Creating Sequence diagrams with UML tools can be incomplete, inconsistent, and incorrect. It also requires expertise, effort, and time. With model transformation technology, this paper presents an approach to automate the generation of UML Sequence diagrams from Use Case Description and Class diagrams. ATL is used as the model transformation language for converting the source metamodels of Use Case description and Class diagrams to the target metamodel of Sequence diagram. The resulting file in XMI format is then transformed by XSLT to another XMI file that suits for rendering the image of Sequence diagram as the final output. The proposed method would result in the improvement of software process. Rather than constructing the models from scratch during the different development life cycle stages, model transformations enable the reuse of information that was once modeled, as well as enhance the consistency among the models representing different views of the system.

Index Terms—model-driven, model transformation, sequence diagram, process improvement

I. INTRODUCTION

Today, UML is accepted by the Object Management Group (OMG) as the standard for modeling object-oriented programs. Several diagrams are defined to support the design of object-oriented systems. One of the UML diagrams includes the Sequence diagram which is used primarily to show the interactions between objects in the sequential order that those interactions occur. The diagrams allow the designer to specify the sequence of messages sent between objects in collaboration. As opposed to Collaboration diagrams, Sequence diagrams emphasize the sequence of the messages rather than the relationships between the objects.

UML models had been improved by the OMG to be capable of delivering Model Driven Architecture (MDA), i.e. the UML had to function as a more model driven notation. Model driven describes an approach to software development whereby models are used as the primary source for documenting, analyzing, designing, constructing, deploying, and maintaining a system. The promotion of MDA as an architectural framework for software development is one of the major initiatives accomplished by the OMG to help reduce complexity, lower costs, and hasten the introduction of new software applications.

Metamodeling and model transformations are the key concepts in Model Driven Development (MDD) approaches as they provide a mechanism for automated development of well-structured and maintainable systems [1]. Metamodeling provides a means of describing models with complete and precise specification. Different models represent different views of the system, and they are constructed conforming to their metamodels. A model transformation is the process of converting a source model into a target model via a model transformation language. The current well-known transformation languages include QVT (Query/View/Transformation) and ATL (ATLAS Transformation Language). Model transformations play a role to create new models based on the existing information throughout the MDD process. Rather than constructing the models from scratch during the different development life cycle stages, model transformations enable the reuse of information that was once modeled, as well as enhance the consistency among the models representing different views of the system.

This article presents a method to automate the generation of UML Sequence diagrams from Use Case Description (UCD) and Class diagrams. With a set of rules defined in the chosen model transformation language—ATL, the source metamodels of Use Case Description and Class diagrams are converted to the target metamodel of Sequence diagram. The resulting file in XMI format is then transformed by XSLT (eXtensible Stylesheet Language Transformations) to another XMI file that suits for rendering the image of Sequence diagram via the visualization program.

II. MODEL DRIVEN DEVELOPMENT

MDD is based on several concepts and technologies like model, metamodel, meta-metamodel, Model Driven Architecture, and model transformation. A model is an abstract representation of a system defined in a modeling language. Models are the primary artifacts of the MDD process and they represent the system on different levels of abstraction. A model contains enough details for (semi) automatic generation of executable code.

A. Model Transformation

Meta-model is the construction of a collection of "concepts" within a certain model [2]. A model is an abstraction of reality in the real world, while a metamodel is another abstraction highlighting properties of the model itself. A model conforms to its metamodel similar to the way
that a computer program conforms to the grammar of the programming language in which it is written.

The Meta-Object Facility (MOF) [3] can be regarded as an OMG standard to write metamodels. MOF originated in the Unified Modeling Language as a metamodeling architecture to define the UML. MOF is designed as a four-layered architecture as shown in Fig. 1. It provides a meta-metamodel at the top layer, called the M3-layer. The MOF meta-metamodel is referred as the MOF Model. This M3-model is the language used by MOF to build metamodels, called M2-models. An example of a Level 2 MOF model is the UML metamodel, which is the model describing the UML itself. MOF metamodels are usually modeled as UML Class diagrams. These M2-models describe elements of the M1-layer, and thus M1-models. Examples of M1-models include those models created in UML, such as Class and Sequence diagrams. The last layer is the M0-layer or data layer. It is used to describe real world objects, such as code and documentation. The XML Metadata Interchange (XMI) [4] is a standard format for exchanging information about MOF compliant models (M3, M2, M1 Levels) using the eXtensible Markup Language (XML). It includes information about elements in a model and their relationships.

The MOF specification is the foundation of the OMG standard environment where models can be created, integrated, and transformed into different formats. The OMG’s Model Driven Architecture relies on the MOF to integrate the modeling steps and provide the model transformations.

Model transformations aim to provide a means to produce target models from a number of source models in the scope of Model Driven Engineering (MDE). MDE is a software development methodology that is mainly concerned with the evolution of models as a means of developing software by focusing on models. Some of the well-known MDE initiatives include the OMG’s initiative of Model Driven Architecture, and the Eclipse ecosystem of programming and modeling tools (Eclipse Modeling Framework– EMF) [5].

Model transformations in MDE follow a common pattern as depicted in Fig. 2. A model conforms to a metamodel, while a metamodel conforms to a meta-metamodel. The transformation model defines how to generate models that conform to a particular metamodel from models that conform to another metamodel or the same metamodel. From Fig. 2, the transformation model M_t transforms M_a to M_b. M_a, M_l, M_m, and M_b are the models conforming to MM_a, MM_l, and MM_m, respectively. The three metamodels conform to a common meta-metamodel MMM.

### B. Atlas Transformation Language (ATL)

ATL [7] is a model transformation language and toolkit. It is one of the most popular and widely used model transformation languages. ATL is a hybrid model transformation language containing a mixture of declarative and imperative constructs based on Object Constraint Language (OCL) for writing expressions. ATL transformations are unidirectional, i.e. operating on read-only source models and producing write-only target models. During the execution of a transformation, source models can be navigated but changes are not allowed. Target models cannot be navigated.

ATL provides a means to produce a number of target models from a set of source models. An ATL transformation program is composed of rules that define how source model elements are matched and navigated to create and initialize the elements of the target models. Developers can define the way source model elements must be matched and navigated in order to initialize the target model elements. ATL is a hybrid of declarative and imperative. The preferred style of transformation writing is declarative, providing that simple mappings can be expressed simply. However, imperative constructs are provided so that complex mappings can still be specified.

Fig. 3 illustrates when ATL is applied in the context of the transformation pattern. A source model M_a is transformed into a target model M_b according to a transformation definition mma2mbatl written in ATL. The transformation definition is a model conforming to the ATL metamodel (Fig. 4). All metamodels conform to MOF.

ATL is developed on Eclipse platform. Eclipse platform defines EMF framework which is a modeling framework and code generation facility for building tools and other applications based on a structured data model. The core EMF framework includes a metamodel (ECORE) for describing models and runtime support for the models including change notification, persistence support with default XMI serialization, and a very efficient reflective API for manipulating EMF objects generically.

ECORE is the core meta-model at the heart of EMF. It allows expressing other models by leveraging its constructs. ECORE is also its own meta-model because ECORE is defined in terms of itself.
The source metamodels of Use Case Description (Fig. 8) and Class diagram (Fig. 10), accompanied with the target metamodel of Sequence diagram (Fig. 11) are used during the ATL transformation process. This research has applied the approach presented in [10], [11] for creating a Sequence diagram from the messages in UCD based on the knowledge of natural language and the principles of artificial intelligence.

In addition, a set of mapping rules is defined as summarized in Table 1. Each rule covers the construction of the component of Sequence diagram from the source models. That is,

Rule 1: Create Message

IF (UCD)Sentence.verb match any (CL)Operation.name THEN
(SQ)Message.name = (CL)Operation.name
ELSE
(SQ)Message.name = (UCD)Sentense.verb
END IF

Rule 2: Create Lifeline

IF (UCD)Sentence.verb match any (CL)Operation.name THEN
(SQ)Lifeline.name = (CL)Class.name
ELSE
(SQ)Lifeline.name = (UCD)Sentense.object
END IF

Rule 3: Create Sender receiving message

IF (UCD)Sentence.noun match any (CL)Class.name THEN
start = (CL)Class.name
ELSE
/*create new Lifeline using Sentense.noun*/
start = (UCD)Sentense.noun
END IF

Rule 4: Create Receiver receiving message

IF (UCD)Sentence.object match any (CL)Class.name THEN
finish = (CL)Class.name
ELSE
/*create new Lifeline using Sentense.object*/
start = (UCD)Sentense.object
END IF

Rule 5: Create Combined Fragment having value of alternatives

IF (UCD)Item.name match 'Alternative flows and exceptions' and (UCD)flowOfEvent.sequenceNumber exists in Item.value THEN
(SQ)Combinedfragment.interactionOperator = 'alt'
END IF

Rule 6: Create Combined Fragment having value of options

IF (UCD)Item.name match 'Alternative flows and exceptions' and (UCD)flowOfEvent.sequenceNumber exists in Item.value THEN
(SQ)Combinedfragment.interactionOperator = 'opt'
END IF

Rule 7: Create Combined Fragment having value of loops

IF (UCD)Alternater.name match 'loop' THEN
(SQ)Combinedfragment.interactionOperator = 'loop'
END IF

III. IMPLEMENTATION

The process of model transformation consists of four main steps as illustrated in Fig. 5. Details are briefly explained in the following subsections.

1. Create Source Models

In this research, the input of Use Case and Class diagrams are created using Visual Paradigm v. 8, that supports UML2. The diagrams created with Visual Paradigm can be exported in XMI-format files (.uml). Moreover, Visual Paradigm provides the feature that supports the insertion of descriptions into Use Case diagrams. The Use Case diagram with inserted descriptions will then be exported in XMI format (usecaseWithDesc.uml), and transformed to the target model (usecaseDesc.uml) with ATL transformation as shown in Fig. 6. A set of mapping rules is defined, together with the source metamodel of Use Case (Fig. 7) and the target metamodel of Use Case Description (Fig. 8) are created to support the ATL transformation process. Since the metamodel of Use Case Description is not defined as a standard of the OMG, the method how to build the UCD metamodel presented in [9] is adopted in this work.

2. ATL Transformation

The XMI files of Use Case Description and Class diagram are input to the ATL transformation for generating the output XMI file of Sequence diagram as illustrated in Fig. 9.

<td>&lt;Item&gt;</td>
</tr>
</tbody>
</table>

<sup>1</sup>EClass is represents a class, with zero or more attributes and zero or more references.

<sup>2</sup>EAttribute is represents an attribute which has a name and a type.
3. XSLT Transformation

The XMI format of Sequence diagram as output from the previous step still cannot be image rendered. Another transformation process (Fig. 12) is required to construct the XMI format that suits for image rendering.

![XSLT Transformation Process Diagram](image)

Fig. 12. XSLT transformation process.

4. Visualization

The output XMI-format file (sequenceRender.uml) of Sequence diagram from the previous step is input to the visualization tool, Visual Paradigm, for generating the image of Sequence diagram that conforms to UML standard of OMG.

IV. CONCLUSION

UML Sequence diagrams are widely used to describe interactions among classes in terms of an exchange of messages over time. They clearly display the sequence of events, show when objects are created and destroyed, are excellent at depicting concurrent operations, and help hunting down race conditions. However, the task of creating Sequence diagrams is error-prone and consumes effort and time. With model transformation technology, this article presents a method and develops a prototype to facilitate the generation of UML Sequence diagrams from UCD and Class diagrams. The tool has been developed based on Eclipse Modeling Tools (Kepler-SR1), and ATL is used as the model transformation language. The ATL scripts containing a set of mapping rules are created and executed using Eclipse Modeling IDE. Two ATL plugins are implemented and installed as the extension of Eclipse Modeling IDE. When applying model transformation, if the target model conforms to the target metamodel specification, then the model transformation is syntactically correct. Since the target metamodel specification of the Sequence diagram in this work is defined based on the OMG standard, the generated Sequence diagrams are thus syntactically correct.
